## Abstract

*Clostridium difficile* is a Gram-positive obligate anaerobic bacterium that recognized an important pathogen of humans. The present study aimed to evaluate the intestinal level of neutrophil gelatinase-associated lipocalin (NGAL) in patients with *C. difficile* infection (CDI) as a disease activity marker in the south of Iran. This cross-sectional study conducted from October 2017 to June 2018 on patients referred to Nemazee and Amir Hospital in Shiraz, South of Iran. Patients less than two years old were excluded from the study. The study population was consist of 46 cases (Symptomatic patients that confirmed as a CDI), and 21 control individuals (Asymptomatic patients colonized by *C. difficile*). *C. difficile* isolates were identified by conventional microbiological producers and amplification of housekeeping gene by PCR method. The level of NGAL was determined by enzyme-linked immunosorbent assay (ELISA) according to the instructions of the kit manufacturer. The results showed that the level of NGAL in symptomatic patients' (case group) was higher than asymptomatic carriers (control group), 5.9 ng/mL vs. 4.1 ng/mL; however the observed difference was not statistically significant. Also, in both groups, the mean level of NGAL was significantly higher in patients with gastrointestinal diseases than others. In summary, despite all the limitations, the results of the present study indicate that the intestinal level of NGAL is a biological indicator of intestinal inflammation, regardless of CDI. However, further study needs to elucidate the role of NGAL in inflammation caused by bacterial infections.

**Keywords:** *Clostridium difficile*; CDI; Lipocalin-2; NGAL; Gastrointestinal diseases

## 1. Introduction

*Clostridium difficile* is a Gram-positive obligate anaerobic bacterium that recognized an important pathogen of humans. The organism can cause serious diseases such as pseudomembranous colitis (PMC), toxic megacolon, and perforation of the colon [1, 2]. *C. difficile* is responsible for the majority of cases of nosocomial diarrhea [3]. Due to spore production,

they are often highly resistant to sterilizations and disinfectants which become them a successful healthcare-associated pathogen [4].

Neutrophil gelatinase-associated lipocalin (NGAL) also known as Lipocalin-2 (LCN2) belongs to a family of small secretory proteins that are expressed by different types of cells, the richest source of which is neutrophils [5, 6]. The results of experiments show a

systematic increase in the expression level of LCN2 in various models of colitis, including human inflammatory bowel diseases (IBD) [7]. Besides, human lipocalin has been reported to be increased in patients with ulcerative colitis [7]. Recently, it has been shown that LCN2 is a real-time indicator for kidney disease and meets all the criteria required for a biomarker [8]. Expression of LCN2 in adipose tissue has been increased in various experimental models of obesity and obese individuals, indicating that LCN2 may be involved in inflammatory disorders [7]. Chassaing et al. introduced the LCN2 in the stool as an indicator to identify inflammation caused by inflammatory bowel disease, which could be linked to various intestinal infections and used as a biomarker index [7, 9].

The present study aimed to evaluate the intestinal level of NGAL in patients with *C. difficile* infection (CDI) as a disease activity marker in the south of Iran.

## 2. Materials and Methods

### 2.1. Study design

This cross-sectional study conducted from October 2017 to June 2018 on patients referred to Nemazee and Amir Hospital in Shiraz, South of Iran. Patients less than two years old were excluded from the study. The study population was consist of 46 cases (Symptomatic patients that confirmed as a CDI), and 21 control individuals (Asymptomatic patients colonized by *C. difficile*). *C. difficile* were identified by conventional microbiological producers including characteristics on cycloserine-cefoxitin fructose agar (CCFA) (MAST Diagnostic, UK) and amplification of triose phosphate isomerase (*tpi*) housekeeping gene by PCR method [10, 11]. This study was following the declaration of Helsinki and ethical permission was sought from the institutional Ethics Committee of Shiraz University of Medical Sciences (Approval No. IR.SUMS.REC.1396.S872).

### 2.2. Measurement of NGAL level

The level of NGAL was determined by enzyme-linked immunosorbent assay (ELISA) according to the instructions of the Lipocalin-2/NGAL Human ELISA kit manufacturer with a detection limit of 0.02 ng/mL (BioVendor, Czech Republic). The samples were diluted to a ratio of 1:10 according to the kit protocol and previous studies in this field. After performing the ELISA test preparation steps, the Optical density of each well was read with an ELISA reader at a wavelength of 450 nm and the results were reported in

ng/mL. The final result was calculated by multiplying the dilution coefficient at the concentration reported by the device.

### 2.3. Statistical analysis

The analysis was performed by using SPSS™ software, version 21.0 (IBM Co., Armonk, NY, USA). The results are presented as descriptive statistics in terms of relative frequency. Values were expressed as the mean ± standard deviation (continuous variables) or percentages of the group (categorical variables). The paired *t*-tests were used to compare means, and a *P* value <0.05 was considered as statistically significant.

## 3. Results

Totally, 46 symptomatic cases consist of 52.2% males and 47.8% females with a mean age of 31.4±24.6 year, and 21 asymptomatic controls consist of 52.4% males and 47.6% females with a mean age of 43.1±23.1 year were included. The distribution of underlying diseases are shown in Table 1.

The results showed that the level of LCN2 in symptomatic patients' (case group) was higher than asymptomatic carriers (control group), 5.9 ng/mL vs. 4.1 ng/mL; however the observed difference was not statistically significant (Figure 1).

To determine the relationship between NGAL levels and gastrointestinal diseases, the mean level of NGAL in symptomatic patients with ulcerative colitis, gastroenteritis, colorectal cancer, and Crohn's was compared with the patients with non-gastrointestinal diseases. As shown in Figure 2, the mean level of NGAL was significantly higher in patients with gastrointestinal diseases than others (12.6 ng/mL vs. 3.0 ng/mL; *P* <0.001).

Also, in asymptomatic carriers (Figure 3), the mean level of NGAL was significantly higher in patients with gastrointestinal diseases than in others (8.1 ng/mL vs. 2.0 ng/mL; *P* <0.009).

## 4. Discussion

In recent years, the prevalence of CDI has increased significantly and has become a growing health concern, especially in hospitals [12]. Hospital-acquired CDI can be a consequence of the development of the disease due to colonization with *C. difficile* or exposure to a new strain transmitted from patients or the environment [13].

Table 1. The distribution of underlying diseases among studied patients

Underlying disease	Case (symptomatic)		Control (asymptomatic)	
	Frequency	Percent	Frequency	Percent
Ulcerative colitis (UC)	8	17.4	1	4.8
Acute lymphoblastic leukemia (ALL)	5	10.9	2	9.5
Liver transplantation	5	10.9	3	14.3
Gastroenteritis	5	10.9	4	19.0
Acute myeloid leukemia (AML)	1	2.2	-	-
Kidney failure	4	8.7	2	9.5
Diabetes mellitus (DM)	2	4.3	-	-
Metabolic disorder	2	4.3	-	-
Pneumonia	2	4.3	-	-
Autoimmune hepatitis	1	2.2	-	-
Chronic lymphocytic leukemia (CLL)	1	2.2	1	4.8
Colon Cancer	1	2.2	-	-
Crohn's	1	2.2	1	4.8
Glaucoma	1	2.2	-	-
Liver neoplasms	1	2.2	-	-
Multiple myeloma	1	2.2	-	-
Myelodysplastic syndromes (MDS)	1	2.2	-	-
Non-Hodgkin lymphoma (NHL)	1	2.2	-	-
Optic Glioma	1	2.2	-	-
Osteosarcoma	1	2.2	-	-
Wilm's Tumor	1	2.2	-	-
Chronic myelogenous leukemia (CML)	-	-	2	9.5
Aspiration pneumonia	-	-	1	4.8
GI vasculitis	-	-	1	4.8
Guillain-Barre	-	-	1	4.8
Kidney transplantation	-	-	1	4.8
Mushroom poisoning	-	-	1	4.8
Total	46	100	21	100

Figure 2: Comparison the intestinal level of NGAL in patients with gastrointestinal diseases and other patients among the case group (symptomatic)

**Figure 3.** Comparison the intestinal level of NGAL in patients with gastrointestinal diseases and other patients among the control group (asymptomatic carriers)

In a study by Chassaing et al., suggested that the LCN2 in feces can be an indicator for the identification of inflammation caused by IBD in mouse models. Also, they suggest that LCN2 could be linked to other intestinal infections, but to introduce as a biomarker needs to future examination [7].

In the present study, there was no statistically significant difference between the levels of LCN2 among case and control groups. However, the intestinal level of LCN2 in both groups was significantly higher in people with gastrointestinal diseases. Previously, Xiu Guo et al. had shown that in infected animal models with pathogenic strains of *Escherichia coli*, the level of LCN2 in the jejunum increased rapidly [14]. These results indicate that LCN2 as a proinflammatory factor can be expressed independently of the presence of bacterial infection, but the presence of any intestinal inflammation can significantly promote its production. It has been suggested that alteration in the level of LCN2 can balance the level of the intestinal microbiome and the host response to infection [7, 15]. It has also been shown that increasing LCN2 levels helps to limit infection by inhibiting siderophore receptors and reducing pathogen access to iron [14].

The main limitations including the fact that the present study is a cross-sectional study that was performed only on patients with antibiotic-related diarrhea and not all diarrhea patients were tested for the presence of *C. difficile*.

In summary, despite all the limitations, the results of the present study indicate that the intestinal level of NGAL is a biological indicator of intestinal inflammation, regardless of CDI. However, further study need to elucidate the role of NGAL in inflammation caused by bacterial infections.

#### Author Contributions

Conception or design of the work: HS; Data collection: HS; Data analysis and interpretation: MH, HS; Drafting the article: MH, HS; Critical revision of the article: MH, HS. All authors read and approved the final version of manuscript.

#### Conflict of Interests

The authors declare that they have no conflicts of interest.

#### Ethical declarations

The study design approved by the local Ethics Committee of Shiraz University of Medical Sciences (Approval No. IR.SUMS.REC.1396.S872).

#### Financial Support

This study was supported by Shiraz University of Medical Sciences with grant No. 96-14947.
